

Kubernetes Internal Load Balancer

- Using an internal load balancer, the Kubernetes service type internal load balancer will have an IP address from a subnet
- Requires annotation: `service.beta.kubernetes.io/azure-load-balancer-internal: "true"`
- Azure provisions by default an Azure Internal Load Balancer resource
- By default, it gets created within AKS's subnet, but another subnet can be specified using an annotation
- You can also attach a private link and use a private end point with the internal load balancer
- AKSs' identity needs write authorization at AKS's subnet level
