

Using Application Gateway Ingress Controller (AGIC)

- **Application Gateway** is an Azure service that can be seen as a **load balancer for web traffic**
- **AGIC integrates** Azure's native **Application Gateway** and **AKS** to expose apps to the Internet
- **AGIC** continuously **updates** the **Application Gateway while monitoring the Kubernetes cluster** to expose particular services to the internet
- AGIC is a **pod** in the AKS cluster that **translates Kubernetes resources to Application Gateway-specific configuration**
- **AGIC** helps **reduce the requirement for another load balancer or public IP** in front of the AKS
- Application Gateway and pods **communicate privately**
- **Web Application Firewall (WAF)** protects web applications against common exploits and vulnerabilities
- **AGIC** can be **implemented** via a managed **add-on** or **helm**
- **Greenfield** installations create both **AKS** and the **Application Gateway** from **scratch**
- **Brownfield** installations are installed on an **AKS cluster with an existing Application Gateway**
