

Use Azure Front Door to route traffic between multiple AKS clusters

- **Azure Front Door** is a cloud-based service that provides a secure and scalable **entry point** for web applications
- It **acts as a global load balancer and traffic manager**, routing incoming traffic to the closest available backend server
- It provides features like HTTPS, URL-based routing, session affinity, and caching
- Azure Front Door **routing methods**:
 - **Latency**-based routing sends requests to the origins with the lowest network latency
 - **Priority** routing configures a primary origin to handle all traffic, with secondary origins used as a fallback
 - **Weighted** routing divides traffic among origins according to their weight coefficients
 - **Session Affinity** guarantees that requests from the same end user are directed to the same origin
