

Seccomp in AKS

- Seccomp (secure computing mode) is a Linux kernel feature that restricts the system calls a process can make during its execution
- A system call is a way for a process to request a service from the operating system kernel
- It reduces the attack surface of an application by limiting it to a subset of the available system calls. Seccomp filters can be applied to individual processes, containers, or the entire system
- **Difference between AppArmor and Seccomp:**
 - AppArmor is a way to restricts the actions that a process or application can perform
 - Seccomp is a security mechanism that allows restricting the system calls that a process can make
- **Real world association**
 - Seccomp is like setting up rules for a child to keep them safe by limiting what they can do around the house
- Most Linux distributions come pre-configured with a set of seccomp filters
- Seccomp is natively supported for AKS nodes
- Seccomp filters can be added at the node level manually or using a DaemonSet and then referenced at the pod level using securityContext
