

KEDA in AKS

- **KEDA** (Kubernetes-based Event Driven Autoscaling) is a **Kubernetes-based open-source component for event-driven autoscaling of workloads**
- KEDA **scales workloads dynamically based on the number of events** they receive
- KEDA extends Kubernetes with a custom resource definition (CRD) called "**ScaledObject**" to **describe how applications should be scaled** in response to a specific event
- Event-driven scaling is useful in **scenarios** where workloads receive **bursts of traffic** or handle **high volumes of data**
- **Difference between HPA and KEDA**
 - **HPA** is **metrics-driven** and scales based on **resource utilization** such as CPU and memory
 - **KEDA** is **event-driven** and scales based on the number of **incoming events**
 - **KEDA** can still **make use** of **HPA** for replica scaling
- **KEDA in AKS**
 - **AKS** provides an **add-on to simplify KEDA installation** using the **--enable-keda** flag
 - The AKS KEDA add-on provides **basic** common configuration (**for the moment**), and manual editing of KEDA YAML files is recommended for more customization
